Base R Graphics

Some More Plotting with Base R

Basics of Plotting

Recall,

- Visualization variation (of a single variable):
 - hist() Histograms.
 - barplot() Bargraphs.
- Visualizing covariation (of multiple variables):
 - plot() Scatterplots.
 - boxplot() Boxplots (box-and-whisker plots).

Basics of Plotting

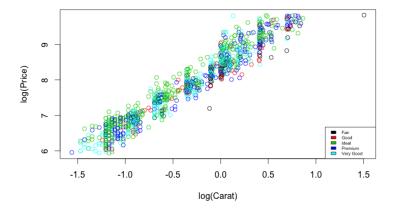

The plot() function.

- The foundation of many of R's graphics functions.
- Often one builds up the graph in stages with plot() as a base.
- Each call to plot() begins a new graph window.
- Takes arguments, called *graphical parameters*, to change various aspects of the plot. (?par)

Diamonds Dataset

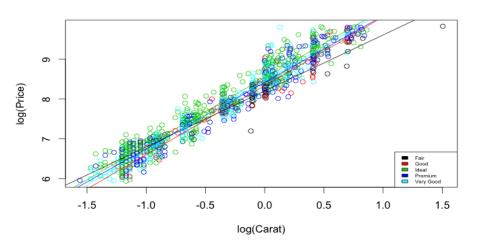

- Recall the diamonds data set. (diamonds.csv)
- Run diamonds <- read.csv("diamonds.csv", as.is = TRUE).

```
> plot(log(diam$carat), log(diam$price), col = diam$cut)
> legend("bottomright", legend = levels(diam$cut),
+ fill = 1:length(levels(diam$cut)), cex = .5)
```

Let's instead plot a regression line for each cut separately.

```
> cuts <- levels(diam$cut)
> col counter <- 1
> for (i in cuts) {
+ this_cut <- diam$cut == i
+ this_data <- diam[this_cut, ]
+ this_lm <- lm(log(this_data$price)
+
                     ~ log(this_data$carat))
   abline(this_lm, col = col_counter)
+
   col_counter <- col_counter + 1
+ }
```

Check Yourself

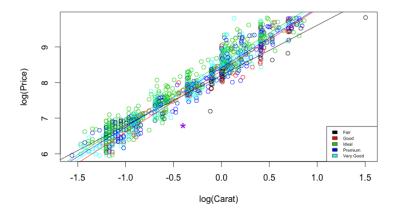

Exercise:

Use the built-in iris dataset.

- Create a new column Setosa that takes a 1 if the iris is a setosa and a 0 otherwise.
- Plot iris Sepal.Width on the x-axis and Sepal.Length on the y-axis. Color the points according to whether the iris is a setosa or not.
- Plot two regression lines on the plot, one for the setosa iris and one for non-setosa iris.

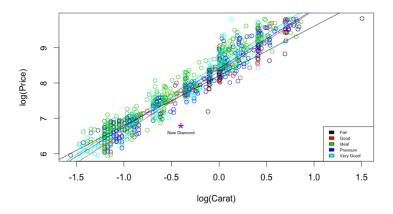

We add a new point for a diamond that is \$898 and 0.67 carats.

> points(-0.4, 6.8, pch = "*", col = "purple")

We add text to the new point we just added.

> text(-0.4, 6.8 - .2, "New Diamond", cex = .5)

Useful Graphical Parameters

The table below lists a selection of R's graphical parameters. More info at http://www.statmethods.net/advgraphs/parameters.html or using ?par.

Parameter	Description
pch	Point Character. Character of the points in the plot.
main	Title of the plot.
xlab, ylab	Axes labels.
lty	Line Type. E.g. 'dashed', 'dotted', etc.
lwd	Line Width. Line width relative to default $= 1$.
cex	Character Expand. Character size relative to default $= 1$.
xlim, ylim	The limits of the axes.
mfrow	Plot figures in an array (e.g. next to each other).
col	Plotting color.

Section II

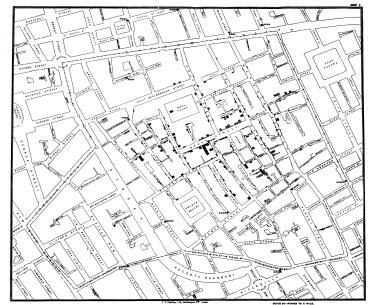

Data Visualization

Section II

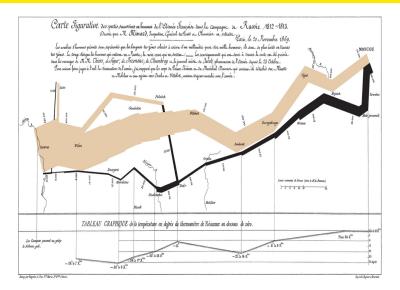

Good Visualizations

In data science, good visualizations should give you more information than you can see in just the data table itself.

Good Visualizations - John Snow 1854 (Wikipedia)

Good Visualizations - Charles Joseph Minard 1896 (Wikipedia)

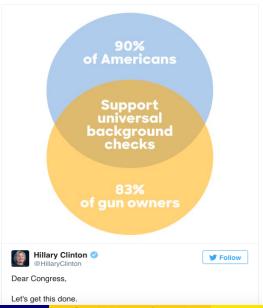

Good Visualizations - Charles Joseph Minard 1896 (Wikipedia)

Minard Graph

Minard shows six variables:

- Number of soldiers,
- Direction of the march,
- Location coordinates,
- Temperature on the return journey,
- Location on dates in November and December.

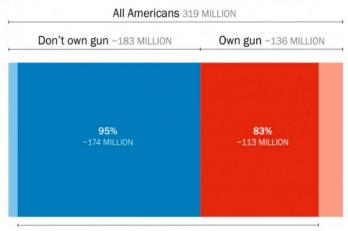

Bad Visualizations - Hillary Clinton

Good Visualizations - Washington Post

Improving the Clinton campaign's terrible graph

Population estimates from the Census Bureau. Gun ownership estimate based on calculations from Gallup compared with Census household data. Percentages based on Clinton campaign figures.

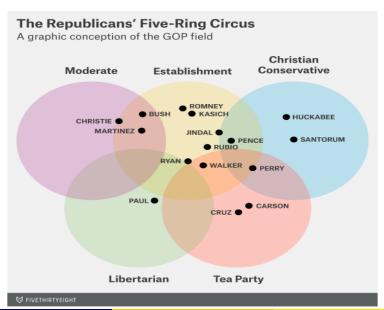

90% support universal background checks ~287 MILLION

Bad Visualizations

Even statisticians are sometimes bad at making visualizations!

Bad Visualizations - Nate Silver

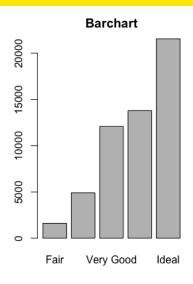

Bad Visualizations - Nate Silver

Candidate	Moderate	Establishment	Christian Conservative	Libertarian	Tea Party
Bush	X	X			
Carson					Х
Christie	X	X			
Cruz					X
Huckabee			X		
Jindal		X	X		
Kasich		X			
Martinez	X	X			
Paul				X	
Pence		X	X		
Perry		X	X		X
Romney		X			
Rubio		X			
Ryan		X			
Santorum			X		
Walker		X			X

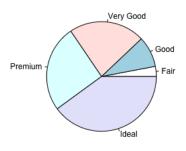

Bad Visualizations

- A piechart is a bad graphic for visualizing categorical data.
- This is a biased opinion from a statistician.
- Statisticians typically do not like pie charts.
- Barcharts display the same information as a piechart and the graphic is easier to interpret.

Barchart vs. Piechart

Pie Chart

Task

Identify what the following function does.

Code

```
> pie.chart <- function(data) {
+ print("I suck")
+ }</pre>
```

Task

Identify what the following function does.

Code

```
> pie.chart <- function(data) {
+ print("I suck")
+ }</pre>
```

```
The pie.chart function prints "I suck"
```

```
> pie.chart(c("Red","Red","Blue"))
```

```
[1] "I suck"
```

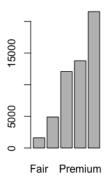

Side note: plots per window

Change graphical parameters

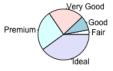

- Use the par() function to change graphical parameters.
- Change plots per window with mfrow
- The default is mfrow=c(1,1)

Barchart vs. Piechart

Barchart

Pie Chart

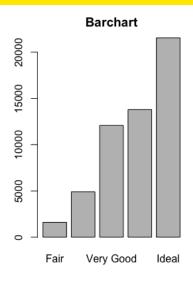

Side note: plot margins

Change graphical parameters

- Change margins with mar or mai
- Note: mar=c(bottom,left,top,right)
- The default is mar=c(5.1, 4.1, 4.1, 2.1))

Barchart vs. Piechart

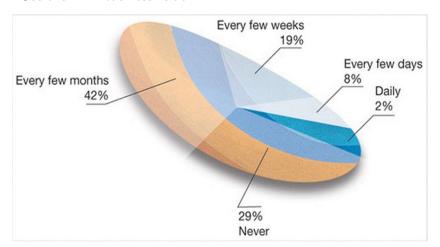

Pie Chart

Bad Visualizations

- Some more bad visualizations
- See the link: businessinsider

Good Visualizations

- Keep things simple in terms of color and presentation!
- Try not adding non-needed dimensions to a plot, i.e., 3D bar chart describing one categorical variable.
- Showing more dimensions on lower a dimensional plot is encouraged,
 i.e, diamond price versus carat split by cut.
- Barcharts are a better way to summarize categorical data compared to piecharts.

Section III

Advanced Visualization Techniques

ggplot2

- R has several systems for making graphs (we've looked at the base R functions).
- ggplot2 is one of the most elegant and flexible.
- ggplot2 uses a coherent system (or 'grammar') for describing and building graphs.

ggplot2

- R has several systems for making graphs (we've looked at the base R functions).
- ggplot2 is one of the most elegant and flexible.
- ggplot2 uses a coherent system (or 'grammar') for describing and building graphs.

Need to run install.packages("ggplot2") now and library("ggplot2") every time you want to use it!

ggplot2

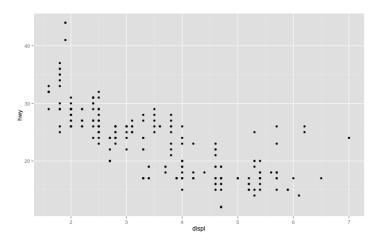

We study ggplot2 using the mpg dataset. Let's try to answer the question: do cars with bigger engines use more fuel than cars with small engines?

ggplot2

We study ggplot2 using the mpg dataset. Let's try to answer the question: do cars with bigger engines use more fuel than cars with small engines?

```
Read about the data using ?mpg.
> dim(mpg)
[1] 234 11
> head(mpg, 3)
# A tibble: 3 x 11
 manufacturer model displ year cyl trans drv
                                                 cty
 <chr>
          <chr> <dbl> <int> <int> <chr> <chr> <chr> 
1 audi
           a4 1.80 1999 4 auto(15) f
                                                  18
                                4 manual(âĂe f
           a4 1.80 1999
                                                    21
2 audi
3 audi a4
                   2.00 2008 4 manual(âĂe f
                                                    20
# ... with 3 more variables: hwy <int>, fl <chr>,
# class <chr>
```

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy))
```

```
Let's break apart the code:
```

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy))
```

Let's break apart the code:

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy))
```

- Begin a plot with ggplot().
 - It creates the coordinate axis that you add to.
 - The first argument is the dataset

Let's break apart the code:

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy))
```

- Begin a plot with ggplot().
 - It creates the coordinate axis that you add to.
 - The first argument is the dataset
- Next you want to add layers to the plot.
 - In our example: geom_point() adds a layer of points.
 - Lots of different geom functions doing different things.

Let's break apart the code:

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy))
```

- Begin a plot with ggplot().
 - It creates the coordinate axis that you add to.
 - The first argument is the dataset
- Next you want to add layers to the plot.
 - In our example: geom_point() adds a layer of points.
 - Lots of different geom functions doing different things.
- geom functions take mapping arguments.
 - Defines how variables in your dataset are mapped to visual properties.
 - Always paired with aes().
 - The x and y arguments specify which variables to map to the axes.

General structure:

```
ggplot(data = <DATA>) +
  <GEOM_FUNCTION>(mapping = aes(<MAPPINGS>))
```

To create a plot, replace the bracketed sections in the code above with a datatset, a geom function, and a set of mappings.

From this template, we can make many different kinds of graphs using ggplot.

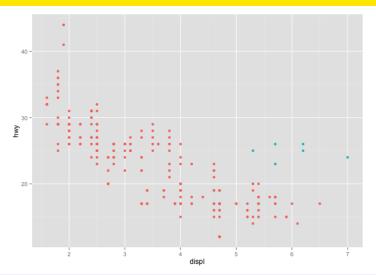

Check Yourself

Tasks

- Plot just ggplot(data = mpg). What do you get?
- Make a scatterplot of hwy vs. cyl.
- Make a scatterplot of class vs. drv. Why is this plot not useful?

we don't use scatterplot to visualize two categorical variable 应该用multiple bargraph

Aesthetic Mappings

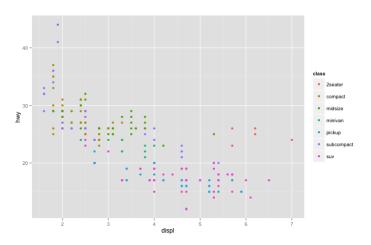

The blue points seem to have a different trend than the rest – possibly hybrids? We study car class to find out.

Aesthetic Mappings

- We can add a third variable to a scatterplot by mapping it to an aesthetic.
- An aesthetic is a visual property of the objects in the plot.
- Things like size, color, shape of points.

Mapping Aesthetics

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x=displ, y=hwy, color=class))
```

Check Yourself

Tasks

- Instead of mapping class to the color aesthetic, map it to the alpha aesthetic or the size aesthetic.
- Instead of mapping class to the color aesthetic, map it to the shape aesthetic. Note that ggplot() will only use 6 shapes at a time. What does this mean for our plot?
- What does the following code do?

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x=displ, y=hwy), color="blue")
```

 Map a continuous variable in the mpg dataset, like cty, to the alpha, shape, and size aesthetics. What does this do?

Facets

- We saw we could add categorical variables to plots using aesthetics.
- Can also do this by splitting the plot into facets, which are subplots that each display one subset of the data.
- Use the fact_wrap() command to facet a plot by a single variable.
- The argument is a formula created with ~ followed by a variable name.

Facets

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy)) +
  facet_wrap(~ class, nrow = 2)
```

Check Yourself

Tasks

 Facet on two variables use the facet_grid() command. An example is the following:

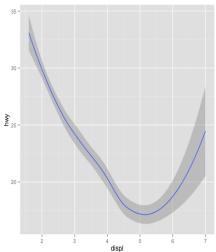

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy)) +
  facet_grid(drv ~ class)
```

What do the empty cells mean?

Determine how to display

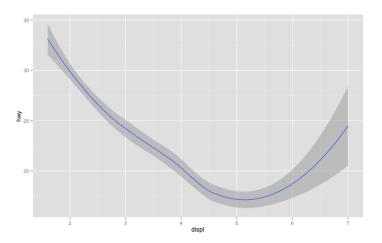

- Look at ?facet_wrap. What do nrow and ncol do? Why doesn't facet_grid() have nrow and ncol arguments? B/c there are two variables so the dimension is already determined
- What happens if you facet on a continuous variable?

- In the previous slide, each plot used a different **visual object** to represent the data.
- Produce this by using different geoms.
- A geom is a geometrical object used to represent data in a plot.
- Often describe plots by the type of geom they use. For example, bar graphs use bar geoms.

```
ggplot(data = mpg) +
  geom_smooth(mapping = aes(x = displ, y = hwy))
```

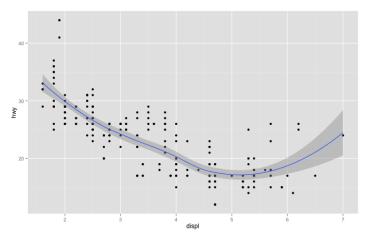

- Every geom takes a mapping argument but not every aesthetic works with every geom.
 - E.g., you can set the shape of a point, but not a line. You can set the linetype of a line.
- ggplot2 has around 30 different geoms.
- Can get help with ?geom_smooth, for example.

Some Commonly-used geoms

geom Name	Used to	Aesthetics
geom_histogram	Visualize a Continuous Variable	х.
geom_bar	Visualize a Discrete Variable	x.
geom_point	Visualize a Two Continuous Variables	x, y.
geom_text	Add Labels to a Plot	x, y, label.
geom_boxplot	Visualize Continuous and Discrete Variables	x, y.
geom_jitter	Visualize a Two Variables	x, y.
many more		

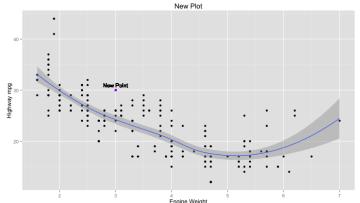

Layering geoms

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy)) +
  geom_smooth(mapping = aes(x = displ, y = hwy))
```

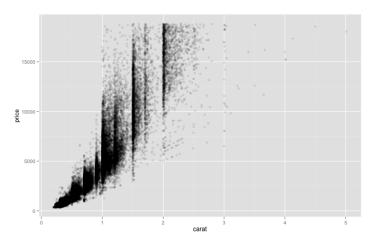

Adding Axis Labels

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy)) +
  geom_smooth(mapping = aes(x = displ, y = hwy)) +
  geom_point(mapping = aes(x=3, y=30), color = "purple") +
  geom_text(mapping = aes(x=3, y=31, label = "New Point"), size=4) -
  labs(title = "New Plot", x = "Engine Weight", y = "Highway mpg")
```

Layering geoms

```
> ggplot(data = diamonds) +
+ geom_point(mapping = aes(x = carat, y = price),
+ alpha = 1/10)
```

Check Yourself

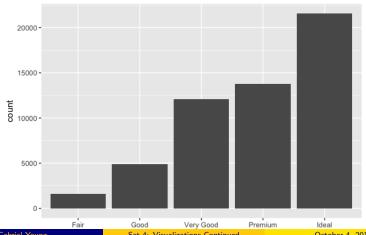

Exercise:

Use the built-in iris dataset.

- Plot iris Sepal.Width on the x-axis and Sepal.Length on the y-axis. Color the points according to whether the iris is a setosa or not.
- Plot two regression lines on the plot, one for the setosa iris and one for non-setosa iris. Hint: Use geom_abline(intercept, slope) or geom_smooth() with method = "lm".

Barplot

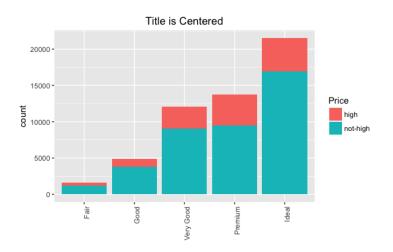

- > ggplot(diamonds)+
- geom_bar(aes(x=cut))

- Split price by the 75th percentile.
- Plot cut and expensive on one barchart.
- Center title
- Remove the word cut from xaxis label.

Barplot

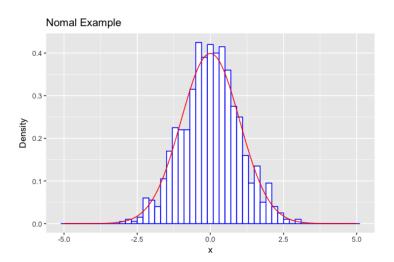

```
> upper <- diamonds$price > quantile(diamonds$price,probs = .
> diamonds$Expensive <- ifelse(upper,"high","not-high")
> theme_update(plot.title = element_text(hjust = 0.5))
> ggplot(data=diamonds) +
+ geom_bar(aes(x=cut,fill=factor(Expensive)))+
+ theme(axis.text.x = element_text(angle = 90, hjust = 1))+
+ labs(title = "Title is Centered",fill="Price",x="")
>
```

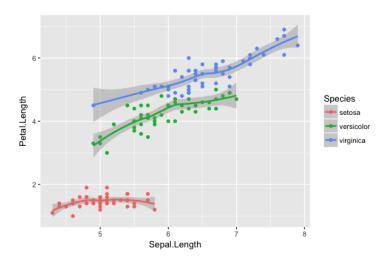

Plot simulated standard normal and its density

```
> x <- seq(-5,5,by=.01)
> hist_data <- data.frame(x.var=rnorm(1000))
> plot_data <- data.frame(x=x,f=dnorm(x))
> ggplot(hist_data)+
+ geom_histogram(mapping=aes(x=x.var,y=..density..),
+ col="blue",fill="white",binwidth=.2)+
+ geom_line(plot_data,mapping = aes(x = x, y = f),
+ col="red")+
+ labs(title = "Nomal Example",x="x",y="Density")
```

A few more examples: Plot simulated normal and its density

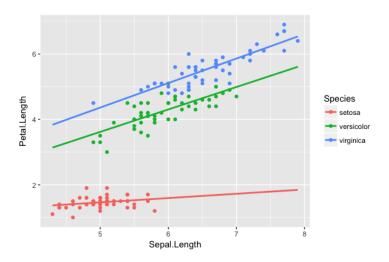

- Plot Petal.Length versus Sepal.Length split by Species
- Fit regression lines to each level of species.
- Match legend and colors accordingly.
- A first attempt!

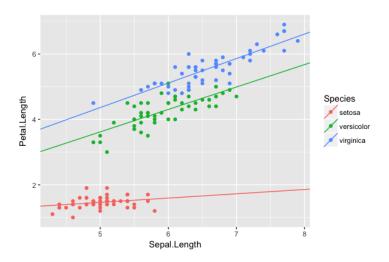

- Plot Petal.Length versus Sepal.Length split by Species
- Fit regression lines to each level of species.
- Match legend and colors accordingly.

```
> ggplot(data=iris)+
+ geom_point(mapping = aes(x=Sepal.Length,y=Petal.Length,
+ color = Species))+
+ geom_smooth(mapping=aes(x=Sepal.Length,y=Petal.Length,
+ color =Species),
+ method=lm,se=FALSE,fullrange=TRUE)
```

iris data: a different approach!

```
> # Define function that extracts intercept and slope
> slopes <- function(df) {</pre>
    return(coef(lm(Petal.Length~Sepal.Length,data=df)))
+ }
> # Define dataframe of the slopes
> line_data <- data.frame(t(sapply(split(iris,iris$Species),</pre>
                                     slopes)),
+
                           Species=levels(iris$Species))
+
> # ggplot
> ggplot(data=iris)+
    geom_point(mapping = aes(x=Sepal.Length,y=Petal.Length,
                              colour = Species))+
+
    geom_abline(data=line_data, aes(slope=Sepal.Length,
+
                                     intercept=X.Intercept.,
                                     colour= Species))
```

A few more examples: multiple time series graph

Data description

- We consider a data set containing information about the world's
 richest people. The data set us taken form the World Top Incomes
 Database (WTID) hosted by the Paris School of Economics
 [http://topincomes.g-mond.parisschoolofeconomics.eu]. This is
 derived from income tax reports, and compiles information about the
 very highest incomes in various countries over time, trying as hard as
 possible to produce numbers that are comparable across time and
 space.
- Open the file and make a new variable (dataframe) containing only the year, "P99", "P99.5" and "P99.9" variables; these are the income levels which put someone at the 99th, 99.5th, and 99.9th, percentile of income.

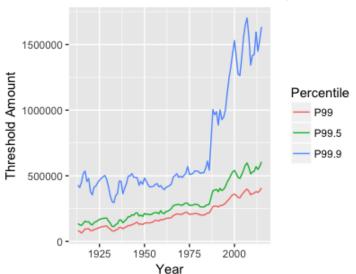

A few more examples: multiple time series graph

```
Data description
> wtid <- read.csv("wtid-report.csv", as.is = TRUE)
> wtid <- wtid[, c("Year", "P99.income.threshold", "P99.5.income
> names(wtid) <- c("Year", "P99", "P99.5", "P99.9")</pre>
> head(wtid)
 Year
       P99 P99.5 P99.9
1 1913 82677.22 135583.5 428630.4
2 1914 76405.62 126910.5 410528.7
3 1915 64409.44 122555.7 451668.3
4 1916 77289.78 138102.3 518327.4
5 1917 95326.69 154537.8 536356.5
6 1918 95202.66 147850.1 457045.0
```

A few more examples: multiple time series graph

```
> n <- length(wtid$Year)</pre>
> wtid.new <- data.frame(Year=rep(wtid$Year,3),</pre>
                          IncomeLevels=c(wtid$P99.
+
                                          wtid$P99.5.
                                          wtid$P99.9).
                          Percentile=c(rep("P99",n),
                                        rep("P99.5",n),
                                        rep("P99.9",n))
> ggplot(data = wtid.new) +
    geom_line(mapping = aes(x = Year, y = IncomeLevels,
                             color=Percentile))+
+
    labs(title = "Thresholds for the Richest People",
         x = "Year", y = "Threshold Amount",
         color="Percentile")
```

Thresholds for the Richest People

Closing remarks

Base R versus ggplot

- ggplot is arguably easier to use than base R.
- The grammar used in ggplot synthesizes with the tidyverse.
- Many professionals prefer ggplot over base R graphics.
- Many professionals prefer base R graphics over ggplot.
- If you know the intricate details of base R graphics, you can construct very beautiful graphs.
